Molecular dynamics simulations are performed for a model glass-forming system at constant volume using Monte Carlo sampling of temperatures in the range of 10 K above and 20 K below the glass transition. Results are obtained for the relaxation times of the energy and the heat flux to a fixed distant sink in the equilibrated glass. The fraction of the heat that flows during a given relaxation process is shown to exhibit considerable variation at different temperatures. The overall relaxation mechanism is elucidated on the basis of the correlation function of the energy flux that accounts for the irreversibility of the process. At low temperatures the energy distribution function of the slow relaxations is non-Gaussian, being peaked at negative energy values, indicating an intermittent character in these relaxation processes. Impaired endogenous antinociception in streptozotocin-treated diabetic rats is associated with altered GABAergic and dopaminergic neurotransmission. The endogenous antinociceptive system is impaired in experimental models of streptozotocin (STZ)-induced diabetes. We aimed to determine whether the reduction of antinociception observed in diabetic animals could be linked to changes in the activity of the neurotransmitter systems that play a critical role in the modulation of pain. Male Wistar rats were divided into control, STZ and STZ+muscimol groups (n=10 in each group). STZ-diabetes was confirmed by the presence of hyperglycaemia. In the ST 82138339de
